

General Description

The 842023 is an Ethernet Clock Generator. For Ethernet applications, a 25MHz crystal is used to generate 250MHz. The 842023 uses IDT 3rd generation low phase noise VCO technology and can achieve <1ps rms phase jitter, easily meeting Ethernet jitter requirements. The 842023 is packaged in a small 8-pin TSSOP, making it ideal for use in systems with limited board space.

Features

- One differential HSTL output pair
- Crystal oscillator interface, 18pF parallel resonant crystal (24.5MHz – 34MHz)
- Output frequency range: 245MHz – 340MHz
- VCO range: 490MHz – 680MHz
- RMS phase jitter at: 250MHz, using a 25MHz crystal (1.875MHz – 20MHz): 0.36ps (typical)
- Full 3.3V or 2.5V output supply modes
- 0°C to 70°C ambient operating temperature
- Available in lead-free (RoHS 6) packaging

Application Information

Crystal Input Interface

The 842023 has been characterized with 18pF parallel resonant crystals. The capacitor values, C1 and C2, shown in *Figure 1* below were determined using a 25MHz, 18pF parallel

resonant crystal and were chosen to minimize the ppm error. The optimum C1 and C2 values can be slightly adjusted for different board layouts.

Figure 1. Crystal Input Interface

Power Supply Filtering Technique

As in any high speed analog circuitry, the power supply pins are vulnerable to random noise. To achieve optimum jitter performance, power supply isolation is required. The 842023 provides separate power supplies to isolate any high switching noise from the outputs to the internal PLL. V_{DD} and V_{DDA} should be individually connected to the power supply plane through vias, and 0.01 μ F bypass capacitors should be used for each pin. *Figure 3* illustrates this for a generic V_{DD} pin and also shows that V_{DDA} requires that an additional 10 Ω resistor along with a 10 μ F bypass capacitor be connected to the V_{DDA} pin.

Schematic Example

Figure 5 shows an example of the 842023 application schematic. In this example, the device is operated at $V_{DD} = 3.3V$. The 18pF parallel resonant 25MHz crystal is used. The $C1 = 22pF$ and $C2 = 22pF$ are recommended for frequency accuracy. For different

board layouts, the $C1$ and $C2$ may be slightly adjusted for optimizing frequency accuracy. An example of HSTL termination is shown in this schematic. Note: Thermal pad (E-pad) must be connected to ground (GND).

Power Considerations

This section provides information on power dissipation and junction temperature for the 842023. Equations and example calculations are also provided.

1. Power Dissipation.

The total power dissipation for the 842023 is the sum of the core power plus the power dissipated in the load(s). The following is the power dissipation for $V_{DD} = 3.3V + 5\% = 3.465V$, which gives worst case results.

NOTE: Please refer to Section 3 for details on calculating power dissipated in the load.

- Power (core)_{MAX} = $V_{DD_MAX} * (I_{DD_MAX} + I_{DDA_MAX}) = 3.465V * (84mA + 11mA) = \mathbf{329.18mW}$
- Power (outputs)_{MAX} = **94.32mW/Loaded Output pair**

Total Power_{MAX} (3.465V, with all outputs switching) = 329.18mW + 94.32mW = **423.49mW**

2. Junction Temperature.

Junction temperature, T_j , is the temperature at the junction of the bond wire and bond pad and directly affects the reliability of the device. The maximum recommended junction temperature is 125°C.

The equation for T_j is as follows: $T_j = \theta_{JA} * Pd_total + T_A$

T_j = Junction Temperature

θ_{JA} = Junction-to-Ambient Thermal Resistance

Pd_total = Total Device Power Dissipation (example calculation is in section 1 above)

T_A = Ambient Temperature

In order to calculate junction temperature, the appropriate junction-to-ambient thermal resistance θ_{JA} must be used. Assuming no air flow and a multi-layer board, the appropriate value is 129.5°C/W per Table 7 below.

Therefore, T_j for an ambient temperature of 70°C with all outputs switching is:

$$70^\circ\text{C} + 0.423\text{W} * 129.5^\circ\text{C/W} = 124.8^\circ\text{C}. \text{ This is below the limit of } 125^\circ\text{C}.$$

This calculation is only an example. T_j will obviously vary depending on the number of loaded outputs, supply voltage, air flow and the type of board (multi-layer).

θ_{JA} vs. Air Flow			
Meters per Second	0	1	2.5
Multi-Layer PCB, JEDEC Standard Test Boards	129.5°C/W	125.5°C/W	123.5°C/W

3. Calculations and Equations.

The purpose of this section is to derive the power dissipated into the load.

HSTL output driver circuit and termination are shown in *Figure 6*.

Figure 6. HSTL Driver Circuit and Termination

To calculate worst case power dissipation into the load, use the following equations which assume a 50Ω load.

Pd_H is power dissipation when the output drives high.

Pd_L is the power dissipation when the output drives low.

$$Pd_H = (V_{OH_MAX}/R_L) * (V_{DD_MAX} - V_{OH_MAX})$$

$$Pd_L = (V_{OL_MAX}/R_L) * (V_{DD_MAX} - V_{OL_MAX})$$

$$Pd_H = (1.8V/50\Omega) * (3.465 - 1.8V) = 59.94mW$$

$$Pd_L = (0.6V/50\Omega) * (3.465 - 0.6V) = 34.38mW$$

$$\text{Total Power Dissipation per output pair} = Pd_H + Pd_L = \mathbf{94.32mW}$$
